Figure 3: Possible Equilibria

## The effect of non-labor income

Figure 4: Effect of Non-Labor Income on the Capacity Curve

Figure 4: Effect of Non-Labor Income on the Capacity Curve

## Distribution of land

## L abor supply as function of land owned

Figure 6: Effective
Reservation Wage

## Different types of equibria

Figure 7: Types of Equilibria

## Policy experiments

- L and R eform:
- MAY improve production and employment (how?)
- CAN improve production without reducing unvoluntary unemployment (how?)
- Is it possible to improve the lot of the poor without decreasing someone' s lot?
- The economy is PARETO EFFICIENT: it is impossible to improve the welfare of someone without decreasing the welfare of someone else
- Minimum wage
- Cash tranfer

## Intra family issues

- Suppose you have a family of two, how should they share resources?

## A dynamic version

- Introduce some dynamics: you can "borrow" or "invest" in your capacity
- W hat may happen to the capacity curve of tomorrow as a function of how you eat today?

## Capacity curve with different nutrition histories

## Capacity curve with different nutrition histories

## Implications

- With better nutrition history, can produce more for each level of nutrition
- Long term effects of short term investments: potentially very high returns
- Returns to investing in children:
- Long term impacts of deworming for a short period of time: $23 \%$ increase in wage for just two extra years with deworming
- Special example: in utero nutrition.

## Labor M arkets

- Suppose an employer could reap the benefit of investing in a worker, what would they now want to do?
- Do they have incentives to do so in a casual labor market?
- Possible arrangements:
- Borrowing: what is the difficulty?
- Long term contracts (bonded labor; slavery: Time on the cross)

## Interpretation

- Resources may not be shared equally within the family
- Gender discrimination
- Widows: "W itch Killings" in A frica (Ted Miguel)
- Children and A dults: households may decide to feed adults. Combined with the dynamic version of capacity curve, this may perpetuate the cycle.

## Conclusion

- Convexity (S shape) of capacity curve can generate poverty trap
- Next time: we will empirically examine the components of the capacity curve and see whether there is evidence of convexity.
- What we need for a poverty trap
- Strong relationship between income and nutrition
- Strong relationship between nutrition and productivity

## References

- Ray, D. (1998). Development Economics. Princeton University Press: Princeton, NJ.
- Dasgupta, P. (1997). N utritional status, the capacity for work, and poverty traps. Journal of Econometrics, 77(1), 5-37.

## From Theory to Mechanisms and Evidence

- This model wants us to think about one particular mechanism of poverty traps based on a non standard production function
- This is not the only form that poverty trap can take but it is a frequent one
- Other sources ?
- fixed investment in small business; increasing returns to education; impact of poverty on productivity through mental health/ability to focus (bandwidth)/environment
- Two ways to think about testing a poverty trap idea of that kind:
- Are the underlying mechanisms present, and is the underlying production function of the right shape?
- Do you see a persistent impact of asset on income growth/productivity that has the right shape

## Formalization of this argument

- For multiple Steady state, the curve that links income today to income tomorrow must intersect the 45 degree line from below.
- $y_{t}=f(g(t)$.
- At steady crossing point, we must have that the product of the two elasticity is above 1.
- This means we must pay attention quantitatively to the elasticity of the relationship between nutrition and income and between income and nutrition.

## How about the purely nutrition based idea? TN Subramanian Critic to Das Gupta and Ray

- Food is too cheap: nutrition based poverty trap cannot be real
- Lottery argument: work some days, don't work some days
- Return to nutrition are not steep enough

## Estimating income effect

- Best descriptive evidence: Deaton Subramanian on calories in India.
- Clear relationship between total expenditures per capita and calorie consumption:
- The relationship does not appear to be non-linear, at least in this range (despite the fact that it is probably an over estimate due to the reverse causality):
- There is also a strong relationship between price of calories and expenditures (see figure, indicating a lot of substitution towards more expensive calories: not clear that households' back is against the wall, even very poor households.
- Since the relationship is more or less log-linear, they proceed to estimate a log-linear relationship, which allows them to add control variables: - Table
- When you become $10 \%$ richer, you spend $7 \%$ more on food, and half of those goes into better food, half of those into more calories.
- Engel curse seems to fall down in India figure

## Is the true relationship even lower? Jensen Miller

- Price Experiment in China: subsidize staple food in two region for randomly selected household. Survey food consumption after a few month.
- In both regions, substitution towards more expensive calories:

```
\Hunan & Guansu
```

- In one region, calories consumption actually worsens. No perceptible improvement on the other items except fat. In the other region, no change in calories consumption
- What can explain these results? What does this imply for the income effect on calorie consumption in this context? This is a sample of urban poor who may eat enough.
- Caveats: short term decrease in food prices: people may be using the windfall to have good food rather than to improve their nutritional status. Long term increase/decrease may have very different impacts.

## Experimental estimates of income effects give higher numbers

- Give Directly: lump sum or monthly transfer
- Randomized evaluation.

|  | $0.24^{* *}$ | -0.19 | 0.35 |
|  | $(0.09)$ | $(0.36)$ |  |
|  |  |  |  |

## Conclusion

- The purely nutrition base poverty trap may not be directly the most relevant (unless we have a HUGE elasticity of productivity with respect to nutrition)
- But there are many other potential source of this S-curve
- Is there a direct evidence of a poverty trap?
